

Automated Email Sender

Algorithm

Step-by-Step Procedure

1. Start the application.
2. Load the sender's email credentials and SMTP server details.
3. Read the recipient list from the input file (CSV, Excel, or text file).
4. Compose the email by setting the subject and message body.
5. Attach files if attachments are specified.
6. Connect securely to the SMTP server.
7. Authenticate using the sender's email credentials.
8. Send the email to each recipient one by one.
9. Record the status (success or failure) for each email.
10. If scheduling is enabled, wait until the specified date and time, then repeat the sending process.
11. Close the SMTP connection after all emails are sent.
12. End the application.

Logic or method Used

The system automates the process of sending emails using Python. It reads recipient details, creates personalized email messages, attaches files if required, and sends them through an SMTP server. The scheduler triggers email delivery at the specified time, while the system logs the delivery status of each email to ensure reliable communication.

Model or Technique Applied

Since this is an automation project

The techniques used are:

- SMTP (Simple Mail Transfer Protocol) for email transmission.
- Python **smtplib** library for connecting to the mail server and sending emails.
- Python **email** library for composing emails and adding attachments.
- Python **schedule** library for scheduling email delivery.
- Python **time** library for managing execution time and recurring tasks.

Process Flow of the System
